

CLAIM AMENDMENTS

IN THE CLAIMS

This listing of the claims will replace all prior versions, and listing, of claims in the application or previous response to office action:

1. (Currently Amended) A computer system, comprising:
a host operable to interface with a network;
a primary storage device operable to interface with the network, the primary storage device including first and second logical units, the first logical unit assigned to store data generated by the host; and
an agent module operable to communicate with the host and the primary storage device, the agent module further operable to:
detect a failure at the first logical unit;
locate backup data from the first logical unit on a backup storage device;
transfer the backup data from the backup storage device to the second logical unit;
and
map the second logical unit to a host address associated with the first logical unit in response to detecting the failure at the first logical unit; and
instruct the host to reboot after the second logical unit has been mapped to the host.

2. (Original) The computer system of Claim 1, wherein the primary storage device comprises a redundant array of independent disks (RAID) device.

3. (Original) The computer system of Claim 1, wherein the detecting comprises receiving notification from the primary storage device of the failure at the first logical unit.

4. (Original) The computer system of Claim 1, wherein the address comprises a world wide name (WWN).

5. (Original) The computer system of Claim 1, wherein the backup storage device comprises a tape drive.

6. (Original) The computer system of Claim 1, further comprising the agent module operable to configure the second logical unit in response to detecting the failure.

7. (Cancelled)

8. (Original) The computer system of Claim 1, wherein the network comprises a fibre channel network.

9. (Original) A computer system for providing automatic data restoration after a storage device failure, comprising:

a plurality of servers operable to interface with a network, the servers including an application server and a backup server;

a plurality of storage devices operable to store data associated with the servers, the storage devices including an application storage device including first and second logical units and a backup storage device interfaced with the backup server, the first logical unit assigned to the application server by using a first logical unit number (LUN) address; and

an agent module associated with the servers and the storage devices, the agent module operable to:

detect a failure at the first logical unit;

assign the second logical unit to the backup server in response to detecting the failure;

instruct the backup server to transfer backup data associated with the first logical unit from the backup storage device to the second logical unit;

map the second logical unit to the application server when the backup data transfer from the backup storage device is complete by using a second LUN address associated with the second logical unit and a server address associated with the application server; and

instruct the application server to reboot after the second logical unit has been mapped to the application server.

10. (Original) The computer system of Claim 9, wherein the application storage device comprises a RAID device.

11. (Original) The computer system of Claim 9, wherein the backup storage device comprises a tape drive.

12. (Original) The computer system of Claim 9, further comprising the agent module operable to configure the second logical unit in response to detecting the failure at the first logical unit.

13. (Original) The computer system of Claim 9, wherein the network comprises a fibre channel network.

14. (Currently Amended) A method for providing automatic data restoration after a storage device failure, comprising:

detecting a failure at a first logical unit operable to store data associated with a host, the host operable to couple to a network;

configuring a second logical unit in response to detecting the failure at the first logical unit, the first and second logical units located on a first storage device operable to couple to the network, wherein:

the first device comprises a RAID device; and wherein
configuring the second logical unit in response to detecting the failure at the first
logical unit comprises instructing the RAID device to create the second logical unit from
one or more spare storage media;
transferring backup data associated with the first logical unit from a second storage
device to the second logical unit; and
mapping the second logical unit to a host address associated with the first logical unit
when the backup data transfer from the second storage device is complete.

15. (Original) The method of Claim 14, further comprising:
communicating the data between the host and the first logical unit via the network; and
communicating the backup data between the first logical unit and the second storage
device via the network.

16. (Original) The method of Claim 14, further comprising locating the backup data
associated with the first logical unit on the second storage device, the backup data copied from
the first logical unit to the second storage device prior to the failure.

17. (Cancelled)

18. (Original) The method of Claim 14, wherein the second storage device comprises
a tape drive.

19. (Original) The method of Claim 14, further comprising instructing the host to
reboot after mapping the second logical unit to the host.

20. (Original) The method of Claim 14, wherein the transferring comprises instructing a backup server interfaced with the second storage device to copy the data from the second storage device to the second logical unit.

21. (Original) The method of Claim 14, wherein the detecting comprises receiving an SNMP message.

22. (Original) The method of Claim 14, further comprising communicating the data via a fibre channel network.

23. (New) A method for providing automatic data restoration after a storage device failure, comprising:

detecting a failure at a first logical unit operable to store data associated with a host, the host operable to couple to a network;

configuring a second logical unit in response to detecting the failure at the first logical unit, the first and second logical units located on a first storage device operable to couple to the network;

transferring backup data associated with the first logical unit from a second storage device to the second logical unit;

mapping the second logical unit to a host address associated with the first logical unit when the backup data transfer from the second storage device is complete; and

instructing the host to reboot after mapping the second logical unit to the host.

24. (New) A method for providing automatic data restoration after a storage device failure, comprising:

detecting a failure at a first logical unit operable to store data associated with a host, the host operable to couple to a network;

configuring a second logical unit in response to detecting the failure at the first logical unit, the first and second logical units located on a first storage device operable to couple to the network;

transferring backup data associated with the first logical unit from a second storage device to the second logical unit, wherein the transferring comprises instructing a backup server interfaced with the second storage device to copy the data from the second storage device to the second logical unit; and

mapping the second logical unit to a host address associated with the first logical unit when the backup data transfer from the second storage device is complete.
